Do you have a proof-of-concept or other example file that reproduces the issue? If so, we would appreciate it if you could attach it.

Thank you for your report. We appreciate you taking the time to share your findings with us.

The behavior you've described is consistent with Apple's documented functionality for `NSWindow.SharingType.none`. As noted in our developer documentation (developer.apple.com/documentation/appkit/nswindow/sharingtype-swift.enum/none), this is a legacy constant that "can cause content to not be available in certain sharing situations." The documentation also specifically advises developers: "Don't use this value to hide or omit content from being captured."

It's also worth noting that, as your own testing demonstrates, applications using this sharing type are not hidden from detection. The `kCGWindowSharingState` property remains readable through the window list API, meaning proctoring or monitoring software can readily identify windows configured with this setting.

Because this behavior aligns with our existing documentation and does not bypass a security boundary, we do not consider this to be a security issue.
